

# Best Evidence Summaries of Topics in Mental Healthcare

**BEST** *in* **MH** *clinical question-answering service*

## Question

For people with dementia, what features and specifications of the physical ward environment are most beneficial to all patient outcomes?

## Clarification of question using *PICO* structure

*Patients:* People with dementia  
*Intervention:* Features and specifications of the physical ward environment  
*Comparator:* Other features and specifications of the physical ward environment  
*Outcome:* All patient outcomes

## **Clinical and research implications**

No clinical implications can be made from the available evidence. The authors of a systematic review suggested that more high-quality studies are needed to assess the effectiveness of the built environment on managing behavioural and psychological symptoms of dementia.

## **What does the evidence say?**

### ***Number of included studies/reviews (number of participants)***

One systematic review (SR) met the inclusion criteria for this BEST summary (Soril et al. 2014).

### ***Main findings***

The SR aimed to assess the effectiveness of built environment interventions, compared with usual care or no intervention, in the management of behavioural and psychological symptoms of dementia (BPSD) among residents in long-term care settings. The search was conducted in June, 2013. The SR authors identified 5 'non-randomised comparative cohort studies' - two of which evaluated change or redesign of existing physical structures or spaces, one that evaluated the impact of adding physical objects or spaces to the existing environment, and two that evaluated the impact of moving residents with dementia into specialised dementia care units/facilities. The authors of the SR reported that only two of the five studies demonstrated improvements in the frequency and/or severity of behavioural and psychological symptoms of dementia. This included one pre-post study that found that unlocking doors to a common courtyard of a specialised care facility led to decreased agitation in residents with dementia, compared with keeping the doors locked. The other study found that relocation of a small sample of 16 residents from a traditional care unit to a specialised dementia care unit within a single long-term care facility resulted in decreased agitation amongst participants, specifically in verbally aggressive behaviour. None of the studies reported worsening of symptoms. No data or statistical results were presented in the SR, so that further detailed information on the results, including size of effects, was not possible to report in this summary.

### ***Authors' conclusions***

The authors concluded that 'the range of built environments is broad, as is the complex and multi-dimensional nature of BPSD. There is inconclusive evidence to suggest a built environment intervention which is clinically superior in long-term care settings'.

### ***Reliability of conclusions/Strength of evidence***

The included SR was well-conducted in terms of specifying clear inclusion criteria, conducting a thorough search of the literature, and minimising reviewer bias. In addition, all the studies were subjected to a quality assessment using published criteria. The results of the studies were, however, not reported in detail; no data or statistical results were presented, and it is not clear if the results were clinically meaningful. Given the lack of robust studies, the authors' cautious conclusion (i.e. that there is inconclusive evidence) appear to reflect the evidence.

## **What do guidelines say?**

Neither National Institute for Health and Care Excellence (NICE) nor Searching of Scottish Intercollegiate Guidelines Network (SIGN) guidelines commented on the most beneficial features and specifications of the physical ward environment for people with dementia.

**Date question received:** 11/03/2015  
**Date searches conducted:** 24/03/2015  
**Date answer completed:** 09/04/2015
